## Press Release

### Waste CO<sub>2</sub> turns into a commodity: ICO2CHEM and the circular economy for industrial CO<sub>2</sub> re-use at Achema 2018

*Converting CO<sub>2</sub> in fossil-free chemical additives and products is now possible - Hall 9.2, D 44.*

7 June 2018 - Decarbonisation is nowadays a key issue in both political and industrial agendas. Due to the high rate of CO<sub>2</sub> emissions to the atmosphere – which are continuously arising all over Europe and worldwide – research is needed to find ways to mitigate such trend. The EU Integrated Strategic Energy Technology Plan – SET – focuses on decarbonisation by means of actions like Carbon Capture and Sequestration (CCS) and Carbon Capture Utilization (CCU) technologies.

And here it comes to **ICO2CHEM**, the EU-funded international project aimed to demonstrate on the field a CCU pathway by catalytically converting CO<sub>2</sub> into chemicals, ready to enter the industry with raw material for chemical additives and plastic production. Achema 2018 is the perfect context to discover how the process industry can take advantage from European innovation and research results, reaching a two-fold effect: reducing the environmental impact of industrial operations and directly producing raw material from CO<sub>2</sub> emissions.

At **Hall 9.2, D 44**. Infraserp Höchst, which will host the plant and Provadis Hochschule, the project partner responsible for the business model development of ICO2CHEM concept, are ready to present to Achema 2018 attendants the technological paradigm and a plant's mock-up which will be displayed for the first time during the international trade fair held in Frankfurt am Main, Germany, from 11-15 June 2018.

This project is funded by the Horizon 2020 Framework Programme of the European Union

**+ Project info:** Started in October 2017, ICO2CHEM has an international partnership made by Finnish German and Italian top level industries, academic and research centres aimed to transform CO<sub>2</sub> in chemicals for high-quality industrial production, enlightening a typically perceived polluting sector, with a brand new environmental friendly pathway.

Moreover, the aim is to develop a new production concept in order to convert CO<sub>2</sub> emissions into value added chemicals with particular reference to the production of so-called white oils and high molecular weight aliphatic waxes – important chemical feedstocks that are nowadays fossil-based only. The technological core of the project is the combination of a Reverse Water Gas Shift reactor (RWGS), coupled with an innovative modular (FT) Fischer-Tropsch reactor. The Industriepark Höchst, in Frankfurt, Germany, will be the hosting place for the containerized pilot plant, which will convert CO<sub>2</sub> to raw materials for chemicals.

The outcome of the process is therefore ready to get in the production of many sectors like primary raw materials, secondary materials, packaging for any field including food and beverage, at disposal of the worldwide consumer brands.

#### **+ Process details:**

The pilot plant will convert CO<sub>2</sub> from a biogas upgrading plant together with industrial H<sub>2</sub> a by-product of a chloro-alkali electrolyzer plant, into highly valuable white oils and high molecular weight aliphatic waxes. The pilot plant consists of innovative RWGS and FT reactors, supplied by INERATEC. The RWGS step will convert CO<sub>2</sub> with H<sub>2</sub> into a synthesis gas mixture (CO + H<sub>2</sub>). The following FT reaction step will convert the synthesis gas into the chemical products. The FT reactor will be equipped with a novel Co-based catalyst with enhanced selectivity and lifetime, supplied by VTT. The project partner Altana will utilize the white oils and wax emulsions as a raw material for chemical products, such as coatings and sealant materials, and benchmark the properties of the raw material against the fossil-based material.

#### **+ Innovation potential:**

ICO2CHEM not only foresees at developing a novel feasible CO<sub>2</sub> economic route but also enlightening further knowledge about the entire process as well as the FT catalyst. The project coordinator VTT will develop a novel Co-based catalyst with enhanced selectivity for specific synthetic hydrocarbons. INERATEC will demonstrate on the field the robustness and reliability of the proposed micro-reactor technology. With the leadership and industrial expertise of ALTANA, the recycled byproduct of the process will be introduced in different chemical markets as those of surface additives, wax additives, defoamers and air release additives, adhesion promoters and coupling agents, viscosity reducers and synthesis of fuels like methane, diesel, jet-fuels, with a significant impact in reducing environmental pollution and emissions.

**ICO2CHEM** is an **EU Horizon 2020** project. It is funded through SPIRE, the European Public-Private Partnership dedicated to innovation in resource and energy efficiency enabled by the process industries. The project partners are **VTT** from Finland, **INERATEC**, **InfraServ Höchst**, **ALTANA**, **Provdavis Hochschule** from Germany, and **Politecnico di Torino** from Italy.
